Figure 1. Dataset.

# Feature engineering - first approach

### AppointmentID

We use this column for count waitingTime feature and delete it.

### Gender

We leave this column with change F/M to O/1

#### Age

We leave this column and drop value < 0 or value > 110.

#### Neighbourhood

We use one hot encoding.

### PatientId, Scholarship, Hipertension, Diabets, Alcoholism, Handcap, SMSRecived

We leave those columns as were.

#### Dates

We create feature like hour, day and month, dayOfWeek from both dates and waitingTime.

### Train-validation-test split

We split data totaly randomly. This is wrong approach, because it can lead to data leakage.

# Feature engineering - second approach

#### Neighbourhood

We create feature "neighbourhood ratio", where add no-show/show ratio to each neighbourhood. We create category "OTHER" for this neighbourhood which had less than X visit (where X was param, default 200).

#### Handcap

We create category "OTHER" for Handcap > 1, because Handcap = 2 has 183 occurrence, Handcap = 3 has 13 occurrence, Handcap = 4 has 3 occurrence.

### PatientId, Scholarship, Hipertension, Diabets, Alcoholism, SMSRecived

We leave those columns as were.

#### Dates

In our second approach we create feature from patient history: "lastShowTime", "sumAppointxD", "DayOfWeekRatio", "NoShowsRatioxD", "RecentNoShows", "sumNoShowsxD", "last-NoShowTime", "sumRecentNoShows"

Figure 2. Sample client after transformation and feature engineering.

We thing about how long should be window of history (param xD). Because if we get all history, the new patient has less records/visits than older patient (with a lot of visits).

#### Train-validation-test split

We draw PatientId which was selected to train, validation, test dataset.

# **Problem with unbalanced data**

In this dataset, we have unbalanced classes.

- No: 0.7981
- **Yes:** 0.2019

We test a few methods to balance data: Random-Over Sampling, Random-Under Sampling, Nearmiss, ADASYN, SMOTETomek

The best result get SMOTETomek, so we used them in final pipeline. We test and validate data also in dataset without balancing.

We test anomaly datection approach too.

# Other transormation

We use pipelines and fit-tranform technic. In our pipeline we have out custom transforer, imputer, scaler and sampler and model.

```
4 pipeline = Pipeline([
       ("custom", MedicalAppointmentsTransformer(neighbourhood_min_count = 200)),
       ("imputer", SimpleImputer(strategy="mean")),
       ("scaler", StandardScaler()),
       ("oversampling", SMOTETomek()),
       ("model", XGBClassifier(random_state=99))
10 ])
```

Figure 3. Example pipelin

# No-show - different approach: feature engineering, ML, DL, anomaly detection and AUTOML models

<sup>2</sup>Orange

# ond approach

| J | е | • |  |
|---|---|---|--|

# Machine learning and Deep learning models

We test a few ML models: Logistic Regression, Decision Tree, Random Forest, XGBoost, Cat-Boost, LigthGBM, SVC, KNN, Naive Bayes and MLP. We select F1 as our metric to evaluate and compare models.

| Model               | F1   | Accuracy | Precision | Recall | ROC  |
|---------------------|------|----------|-----------|--------|------|
| XGBoost             | 0.45 | 0.70     | 0.35      | 0.62   | 0.67 |
| MLP                 | 0.44 | 0.65     | 0.32      | 0.69   | 0.66 |
| SVC                 | 0.43 | 0.65     | 0.32      | 0.68   | 0.66 |
| Logistig Regression | 0.41 | 0.66     | 0.31      | 0.60   | 0.64 |
| Naive Bayes         | 0.40 | 0.61     | 0.29      | 0.65   | 0.63 |
|                     |      |          | -         |        |      |

We test approach to detect no show as anomaly. Unfortunatelly, Isolation forest and autoencoder get worse scores than classic ml models.

F1: 0.25 Accuracy: 0.73 Precision: 0.23 Recall: 0.28

We test a few AutoML tools, the best was Azure AutoML. In our case the best model was RandomForest with StandardScalerWrapper - with f1 = 0.54.

This AutoML have explanations dashboard and we can build responsible AI dashboard.
